# A STUDY OF THE ALIGNMENT OF THE RIT SCALES OF NWEA’S MAP® ASSESSMENTS WITH THE COLLEGE READINESS BENCHMARKS OF EXPLORE®, PLAN®, AND ACT® 

## DECEMBER 2011

Recently, NWEA completed a study to examine the predictive relationship between the RIT scales of NWEA's MAP ${ }^{\oplus}$ assessments in reading, language usage, and mathematics to the college readiness benchmarks of the EXPLORE, PLAN, and ACT achievement tests in reading, English, and mathematics. The EXPLORE, PLAN, and ACT also offer tests in science achievement, but these tests were not included in the current study. The objective of this study was to identify cut scores on the MAP reading, language usage, and general mathematics tests that correspond to the published college readiness benchmarks on the EXPLORE, PLAN, and ACT assessments (ACT, 2010). A secondary objective was to create a series of probability tables that estimate the likelihood of meeting the designated college readiness benchmark, given an observed MAP score.

To conduct the study, we linked together individual EXPLORE, PLAN, and ACT scale scores and NWEA MAP assessment RIT scores for a sample of students who had completed both exams in the same (or a comparable) subject. EXPLORE, PLAN, and ACT scores were provided by NWEA partnering school districts and individually linked to those students' MAP assessment RIT scores from the same (or the prior) testing season. In all, the sample contained over 108,000 matched pairs of scores from 26,000 students from 140 schools in three states. All valid matched data (i.e., data with valid scores and linking IDs) from the resulting sample were included in the analyses; no attempt was made to rebalance the sample in order to simulate a state- or nationally-representative population.

Visual examinations of scatter plots of the data revealed curvilinear relationships between the MAP scale scores and the EXPLORE, PLAN and ACT scale scores. Consequently, a series of curvilinear (quadratic) regression models were fitted to the data, using MAP RIT scores as the single predictor of performance on each of the college readiness tests. MAP assessments in reading and language usage were both fit to predictive models of performance on college readiness tests of English and Reading. MAP mathematics was used to predict mathematics college readiness. In all, fifteen predictive models were fitted. See the Methodology Appendix for a more detailed description of the methods used.

Table Sets 1 and 2 show the estimated cut scores, or minimum equivalent RIT scores corresponding to the college readiness benchmarks on EXPLORE, PLAN, or ACT when taken in the same (spring) or prior (fall) testing seasons. Also shown are the NWEA normative percentile ranks ${ }^{1}$ associated with these MAP

[^1]cut scores. These tables can be used to identify students who might benefit from additional assistance, or who may be at risk of failing to meet these benchmarks. The percentile ranks also provide an indicator of the difficulty of these benchmarks, relative to a nationally representative norming sample. In general, the MAP cut scores associated with the college readiness benchmarks in English range from the $40^{\text {th }}$ to $60^{\text {th }}$ percentiles on the MAP reading and language usage tests, while the college readiness benchmarks in reading and mathematics are higher, ranging primarily from the $70^{\text {th }}$ to $80^{\text {th }}$ percentiles on the MAP assessments reading and mathematics tests, respectively.

The tables in Table Set 3 show the estimated probability of a student meeting the designated college readiness benchmark, based on that student's RIT score taken in the same testing season. These tables provide empirical information about the likelihood of meeting or exceeding the designated college readiness benchmark, given an observed MAP RIT score.

The tables in Table Set 4 show the correlation coefficients and the goodness-of-fit statistics for the regression models used to predict MAP and the corresponding college readiness tests. These statistics show the degree to which MAP scores accurately predicted the PLAN, EXPLORE, and ACT scale scores of the study sample. The reported models show a moderately high correlation between MAP RIT scores and the scores on the college readiness benchmark tests, with correlations ranging from . 66 to .87, but primarily in the range of .75-.80. In general, values at or near 1.0 suggest a perfect predictive relationship, whereas values near 0.0 indicate no predictive relationship. Goodness-of-fit statistics indicate that substantial variation within the observed college readiness benchmark scores can be predicted by MAP RIT scores, with values ranging from 44-76\% of observed variance.

The tables in Table Set 5 show the accuracy of the estimated MAP cut scores in predicting whether students met or exceeded the corresponding college readiness benchmark for the study sample. In general, the estimated MAP cut scores accurately predicted whether or not students would meet the EXPLORE, PLAN, and ACT benchmarks with 75-90\% accuracy. Among incorrect predictions, false negatives (students who were incorrectly predicted NOT to meet the college readiness benchmark) outnumbered false positives (students predicted to meet readiness benchmarks but who failed to do so).

The estimated MAP cut scores in this report provide a basis for making useful predictions about students' likely college readiness status, as measured by EXPLORE, PLAN, and ACT, when MAP is taken within the same (or nearly the same) testing season. However, MAP is not designed to measure identical content as the ACT assessments. MAP assessments are aligned to each state's curriculum standards rather than the curriculum standards of the ACT. Thus while the tests measure much content that would be similar, they do not share a common design. Knowledge of a student's MAP score permits fairly accurate predictions about a student's probable college readiness status, as measured by EXPLORE, PLAN, or ACT.

## TABLE SET 1 - MINIMUM ESTIMATED SAME-SEASON (SPRING) RIT CUT SCORES CORRESPONDING TO COLLEGE READINESS BENCHMARKS ${ }^{2}$

| MAP Mathematics as Predictor |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Percentage of Sample whose College Readiness Status was Accurately Predicted by MAP Score |  |  |  |  |
| Grade | College Readiness Test | Sample Size | Percentage Correctly Predicted | Percentage of False Positives | Percentage of False <br> Negatives |
| 8 | EXPLORE <br> Mathematics | 12753 | 82\% | 4\% | 14\% |
| 10 | PLAN Mathematics | 9516 | 86\% | 4\% | 9\% |
| 11 | ACT Mathematics | 2948 | 91\% | 1\% | 7\% |

${ }^{5}$ Correct predictions refer to the percentage of students in the study sample whose MAP scores accurately indicated their college readiness status on the college readiness test. False positives indicate the percentage of students predicted to be college ready, but who failed to meet the college readiness benchmark. False negatives indicate the percentage incorrectly predicted to fail to meet the college readiness benchmark, but who did.

## APPENDIX 1: METHODOLOGY

This linking study examines the concurrent relationship between EXPLORE/PLAN/ACT and MAP assessments with the goal of publishing benchmarks on the RIT scale that are predictive of the ACT's college readiness benchmarks (ACT, 2010).

Appendix Table 1 describes the three ACT assessments with their respective college readiness targets by content area.

Study Sample
NWEA solicited all known partner districts that administer both the EXPLORE/PLAN/ACT and MAP assessments to participate in this study. While not every eligible partner participated, the final study sample was large enough (unique total student $n=29,417$ ) to proceed with the analysis. Appendix Table 2 contains the distinct sample count.

Appendix Table 2 - Sample Counts

| Test | Grade | Unique <br> State <br> Count | Unique District <br> Count | Unique School <br> Count | Unique Student |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Count |  |  |  |  |  |

Each district's EXPLORE/PLAN/ACT test records were matched to their corresponding MAP data via a robust matching algorithm housed in NWEA's Growth Research Database. The bulk of the study used matched students who took both assessments in same term. In the cases where students took the NWEA MAP test in different terms, we employed the following prioritized matching process.

> Priority 1 - MAP given in SAME term as EXPLORE/PLAN/ACT Priority 2 - MAP test given one term BEFORE EXPLORE/PLAN/ACT
> Priority 3 - MAP test given two terms BEFORE EXPLORE/PLAN/ACT Priority 4 - MAP test given one term AFTER EXPLORE/PLAN/ACT Priority 5 - Map test given two terms AFTER EXPLORE/PLAN/ACT

In order to ensure comparable RIT scores, we took the MAP percentile associated with the RIT score and substituted the RIT score associated with that percentile in the term the EXPLORE/PLAN/ACT was administered. For example, a winter test score under Priority 2 with a percentile of 75 would be substituted for the corresponding spring RIT score associated with the $75^{\text {th }}$ percentile. Appendix Table 3 contains the distribution of unique students by the EXPLORE/PLAN/ACT test, MAP Grade and prioritized matching scheme.

Appendix Table 3 - Prioritized Matching Count (Unique Students) by ACT Test and MAP Grade

## Analysis

The goal of the analysis is to find the statistical model that best describes the scale relationship between EXPLORE/PLAN/ACT and the NWEA MAP assessments. We tested multiple models including Ordinary Least Squares Regression (Linear and Quadratic) and Hierarchical Linear Model (HLM). The best model was determined by correlation ( $r$ ) and overall model fit.

Akaike Information Criterion (AIC) is the measure of model fit we used. Generally speaking, the AIC examines the tradeoffs between model accuracy and complexity whereby the model with the lowest AIC value is said to be the most parsimonious

Separate linear (1a) and quadratic (1b) regression routines were run for each relationship model.

$$
\begin{gathered}
A C T=a+X \beta+e \\
\text { where } X=R I T \\
A C T=a+X \beta+X^{2} \beta+e \\
\text { where } X=R I T
\end{gathered}
$$

Based on the correlations and AIC fit statistics, the quadratic regression best described the shape of the scale relationship (see Appendix Table 4).

Appendix Table 4 - Initial Model Correlations

| Test | Model | Linear Regression |  | Quadratic Regression |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $r$ | AIC | $r$ | AIC |
| ACT | Language Usage to English | 0.71 | 2400 | 0.77 | 2237 |
| ACT | Language Usage to Reading | 0.64 | 2450 | 0.70 | 2330 |
| ACT | Math to Math | 0.73 | 6549 | 0.81 | 5686 |
| ACT | Reading to English | 0.69 | 8457 | 0.75 | 7948 |
| ACT | Reading to Reading | 0.65 | 8513 | 0.72 | 8013 |
| PLAN | Language Usage to English | 0.65 | 12264 | 0.68 | 11813 |
| PLAN | Language Usage to Reading | 0.55 | 13674 | 0.59 | 13306 |
| PLAN | Math to Math | 0.71 | 21874 | 0.74 | 20855 |
| PLAN | Reading to English | 0.63 | 24102 | 0.67 | 23299 |
| PLAN | Reading to Reading | 0.57 | 26343 | 0.62 | 25418 |
| EXPLORE | Language Usage to English | 0.70 | 25133 | 0.75 | 23440 |
| EXPLORE | Language Usage to Reading | 0.59 | 24728 | 0.66 | 23204 |
| EXPLORE | Math to Math | 0.76 | 24878 | 0.77 | 24615 |
| EXPLORE | Reading to English | 0.69 | 29685 | 0.73 | 28068 |
| EXPLORE | Reading to Reading | 0.62 | 28324 | 0.69 | 26121 |

The next step in the analytic process was to determine whether any between-school variation existed in our scale relationships by running a simple unconstrained HLM model (2):

$$
\begin{equation*}
A C T_{i j}=\gamma_{00}+\mu_{0 j}+r_{i j} \tag{2}
\end{equation*}
$$

$$
\begin{array}{cl}
A C T_{i j} & \text { is the ACT/PLAN/EXPLORE score for student } i \text { in school } j ; \\
\gamma_{00} & \text { is the grand mean (students within schools) } \\
\mu_{0 j} & \text { variance in intercept between schools } \\
r_{i j} & \text { within school variance }
\end{array}
$$

Appendix Table 4 contains the Intraclass Correlation Coefficient (ICC) for each test and model. The ICC measures the proportion of variance in the dependent variable $A C T_{i j}$ that is accounted for by our grouping structure.

Appendix Table 5- Intraclass Correlation Coefficients (ICC) by Test and Model

| Test | Model | $\mathrm{t}_{00}$ | $\sigma^{2}$ | ICC |
| :---: | :---: | :---: | :---: | :---: |
| ACT | Language Usage to English | 9.650 | 30.166 | 0.242 |
| ACT | Language Usage to Reading | 6.490 | 29.035 | 0.183 |
| ACT | Math to Math | 2.458 | 16.348 | 0.131 |
| ACT | Reading to English | 6.669 | 29.763 | 0.183 |
| ACT | Reading to Reading | 4.610 | 28.564 | 0.139 |
| Plan | Language Usage to English | 5.478 | 17.651 | 0.237 |
| Plan | Language Usage to Reading | 6.175 | 19.496 | 0.241 |
| Plan | Math to Math | 5.388 | 16.303 | 0.248 |

| Explore | Language Usage to English | 0.979 | 16.793 | 0.055 |
| Explore | Language Usage to Reading | 0.649 | 12.878 | 0.048 |
| Explore | Math to Math | 0.825 | 14.619 | 0.053 |
| Explore | Reading to English | 0.980 | 16.434 | 0.056 |
| Explore | Reading to Reading | 0.787 | 12.815 | 0.058 |

The ICCs offer a somewhat conflicting picture on the appropriateness of using a multilevel model in the case of this study. For instance, the EXPLORE assessments have the least amount of between-group variance (less than six percent) and the nearly the most number grouping levels (between 29 and 51 individual schools depending on the model). While no well-established ICC thresholds exist per se, it would appear the EXPLORE would not be a good candidate when compared to the ACT and PLAN ICCs.

One explanation for the observed differences could be related to the specific analytic sample used. While we could have employed two separate methods (Quadratic for EXPLORE, HLM for ACT and PLAN),
we felt the quadratic model offered transparency and consistency while maintaining good model fit characteristics.

Figures 1 through 3 illustrate the final fitted model for EXPLORE/PLAN/ACT Math to NWEA MAP Math. Each figure contains notes referencing specific sample or estimation characteristics. Please note standardized residuals greater than 2 or less than -2 were removed from the final model to eliminate potential sources of statistical noise. We should also note the MAP assessment measures student performance relative to state content standards rather than discrete college readiness standards. This difference in content alignment could possibility degrade the published regression coefficients between MAP and EXPLORE/PLAN/ACT.

Figure 1 - ACT Math to NWEA Math

The ACT Math scatter plot and residuals exhibit pronounced curvilinear shapes. The sample also becomes sparse toward the top end of the distribution, making those estimates less reliable.

Figure 2 - PLAN Math to NWEA Math

The PLAN Math scatter plot and residuals display the same curvilinear pattern as the ACT but appears to have more variance along the fit line. Like the ACT, the sample also becomes sparse toward the top end of the distribution, making those estimates less reliable.

Figure 3 - EXPLORE Math to NWEA Math

The EXPLORE Math scatter plot and residuals have a slight curvilinear profile especially when compared to the ACT and PLAN assessments. The EXPLORE assessment has a pronounced ceiling effect in reference to the NWEA MAP assessment, meaning the NWEA assessment has more "stretch" than EXPLORE at the eighth grade level.

[^1]:    ${ }^{1}$ Percentile ranks are based on NWEA's 2011 norming study.

[^2]:    ${ }^{2}$ The MAP cut scores shown in these tables are the minimum estimated scores. Meeting the minimum MAP cut score corresponds to a $50 \%$ probability of achieving that benchmark. Use the probabilities in Table Set 3 to determine the appropriate 'target' scores for a desired level of certainty.

[^3]:    ${ }^{3}$ The MAP cut scores shown in these tables are the minimum estimated scores. Meeting the minimum MAP cut score corresponds to a $50 \%$ probability of achieving that benchmark. Use the probabilities in Table Set 3 to determine the appropriate 'target' scores for a desired level of certainty.

[^4]:    ${ }^{4}$ These correlations are comparable to Pearson's $r$ values, except that they denote the extent to which the two scales are related by a quadratic function. Correlations range from 0 to 1 , where 0 indicates no correlation between college readiness test scores and MAP scores, while 1 indicates a completely correlational relationship between scores on the two tests. Goodness of fit statistics indicate the percentage of observed variance accounted for by the quadratic regression model, with $100 \%$ indicating that college readiness test scores can be predicted with full reliability, whereas 0\% indicates no predictability between the two assessments.
